Typical number reading and writing tasks are widely used in the study of cognition and are commonly used in testing. However, when the absolute frequency of the target number is low, performance deteriorates and imprecision in estimation can arise. Given that people have a strong preference for whole numbers, any performance drop below the optimal number range from a statistical point of view may be offset by participants deciding to 'round up', leading to a distorted perception of the accurate number. In five experiments we compared the response of two alphanumeric keyhole models that accounted for an absolute frequency effect, namely maximum-odds, and maximum-odds-rounded. In Experiments 1 and 2, participants were asked to estimate a presented number. Two different tasks were used: maximum-odds (e.g. 2.82) and maximum-odds-rounded (e.g. 2.8). The results obtained by the two models were remarkably similar and the frequency effect for both tasks was well above the error threshold of a two-alternative forced choice response. In Experiment 3, we replicated
